# 1 Introduction

This document details the backend implementation for the DevSecOps PFE. The system is designed as a RESTful API built with Node.js and Express, focused on secure data handling, automated testing, and containerized deployment.

## 2 System Architecture

The backend follows a \*\*Layered Architecture\*\* pattern to separate concerns and improve maintainability.

- **Routes:** Defines API endpoints and maps them to controllers.
- **Controllers:** Handles the request/response logic and orchestration.
- **Models:** Defines the schema and interacts with the PostgreSQL database.
- **Middleware:** Intercepts requests for authentication (JWT) and security (Helmet).

## 3 Folder Structure

```
1 backend/
2     src/
3         controllers/      # Business logic
4             routes/        # API Route definitions
5             models/        # Database schemas (Sequelize/PG)
6             middleware/    # Auth & Security checks
7             app.js          # Entry point
8             config/         # DB & Environment config
9             package.json    # Dependencies & Scripts
10            Dockerfile     # Container configuration
11            .env            # Secret environment variables
```

## 4 Key API Endpoints

The following table summarizes the core authentication and data endpoints:

Method	Endpoint	Description
POST	/api/auth/register	User registration with Bcrypt hashing
POST	/api/auth/login	Returns JWT Access Token
GET	/api/users/profile	Protected user data (JWT required)
GET	/api/health	Health check for monitoring

Table 1: API Endpoint Summary

## 5 DevSecOps Security Measures

As a DevSecOps project, security is integrated into the code level:

- **Data Encryption:** Passwords are never stored in plain text; `bcrypt` is used with a salt factor of 10.
- **JWT Security:** Tokens are signed with a high-entropy secret and include an expiration time.
- **Rate Limiting:** `express-rate-limit` prevents DDoS and brute-force attacks by limiting IPs to 100 requests per 15 minutes.
- **Header Protection:** `Helmet.js` removes the `X-Powered-By` header and sets XSS protection.

## 6 Deployment & Automation

### 6.1 Local Development

```
1 npm install
2 npm run dev
```

### 6.2 Dockerization

The application is containerized to ensure environment parity between development and production.

```
1 # Build the production-ready image
2 docker build -t devsecops-backend .
3
4 # Run with environment variables
5 docker run -p 5000:5000 --env-file .env devsecops-backend
```

Listing 2: Docker Deployment

## 7 Conclusion

The backend provides a secure, scalable foundation for the DevSecOps pipeline. By utilizing industry-standard security middlewares and a containerized approach, the system is ready for automated CI/CD integration.
